Gaining A Dimension: Breaking The Link Between Spatial And Temporal Refinement

Nick Gnedin Andrey Kravtsov Vadim Semenov

### **Adaptive Mesh Refinement**

- Most typical use of AMR:
  - Refinement in space is flexible (I decide where to refine).
  - Refinement is time is not it is fully tied to spatial refinement.

### **Adaptive Time Refinement?**

Special case: no refinement – uniform timestep.

## **Adaptive Time Refinement?**

- Special case: no refinement uniform timestep.
- With timestepping tied to spatial refinement (either uniform or graded), one cell's CFL condition sets timestepping for the whole grid.
- One SN explosition in one GMC in a single galaxy may dictate how to timestep to the rest of the (virtual) universe.
- There is no place for such concentration of power in a modern democratic society!

 Numerical stability only requires the CFL condition to be satisfied in each cell ("weak causality" condition).

 Under weak causality numerical solution is stable, but not necessarily accurate.

 Weak causality may cause temporary artifacts at timestep boundaries.

6

 Artifacts are always at a "cell level" – i.e. hardly noticeable in well resolved flows.

## **Strong vs Weak Causality**

 Artifacts can be eliminated by requiring "strong causality" – that all waves, both linear and nonlinear, propagate correctly.

# **Ensuring Strong Causality: Easy Way**

 It is easy to ensure strong causality at a given time: neighbors of patches stepping with their CFL-limited timestep should co-evolve.

# **Ensuring Strong Causality: Hard Way**

- The easy way does not prevent future CFL violations.
- Timestep for Patch 1 must be modified "midflight".

# **Ensuring Strong Causality: Hard Way**

- The sure way of achieving strong causality is one-sided communications.
- That requires an "execution queue".

Execution queue

#### **Straddling**

 One "message" may not be enough, it may cause "straddling".

### Straddling

- Two ways to deal with straddling:
  - A. Send another message and cause neighbor to drop it timestep.

- A wave of such "drops" can propagate over the simulated volume.
- The wave is guaranteed to converge. It may not be easy to detect the end point of the wave in a distributed application.

### **Straddling**

Two ways to deal with straddling:
B. Bookkeep who sends flux to whom.

 Bookkeeping is complex, especially with refinement.

### What Do We Gain?

Simple Sedov blast wave test. Solution with strong causality is up ~10% different from the one with the uniform timestep, but it is actually more accurate!

### What Do We Gain?

 A variable timestep solution is 10 times faster, but the difference between the two solutions may not disappear in the infinite resolution limit.

#### Conclusions

- Individual timestepping is a useful numerical technique in many (but, of course, not all) applications.
- Insuring "strong causality" (i.e. correct propagation of all waves) is possible, but may require one-sided communication.
- Solutions with variable timesteps may actually be more accurate than ones with uniform timesteps, since in the advection equation the leading order terms vanish for timesteps with local C=1 (for 1<sup>st</sup> and 2<sup>nd</sup> order schemes).
